The genus *Elachistocleis* Parker currently comprises 13 species widely distributed from Panama to central Argentina, east of the Andes (Caramaschi 2010). Because most species are difficult to diagnose and several currently recognized species might represent more than one lineage, tadpoles can contribute to the resolution of taxonomic problems (Rossa-Feres & Nomura 2006).

Tadpoles used in the present study were collected at Escola Agrícola de Jundiá (5° 53' 06.68''S 35° 22' 01.28''W), municipality of Macaíba, Rio Grande do Norte State, Brazil, in June 2010 and March 2011 (collection permits by IBAMA/SISBIO #15363–1). We took two amplexing pairs to the laboratory, where they spawned and allowed us to confirm the identity of tadpoles collected previously in field. Adult frogs were later identified by U. Caramaschi and deposited at the Coleção do Laboratório de Anfíbios e Répteis da UFRN (CLAR-UFRN, AAGARDA 2473, 2474) and Coleção do Museu Nacional (AAGARDA 2471, 2472, Museu Nacional numbers not yet available). We anesthetized tadpoles in 10% ethanol and preserved them in 10% formalin. We took morphometric measurements from fifteen tadpoles at stage 27 and eighteen at stages 32–34 (Gosner 1960) and described them using the terminology and measurements from Altig and McDiarmid (1999). The variables used in this work are listed in Table I. All measurements shown are in millimeters and were taken using a Mytutoyo digital caliper (0.01 mm precision). A voucher lot of tadpoles at stage 27 used in the description was deposited at Museu de Zoologia da Universidade de São Paulo (MZUSP 145201). The tadpole used in the description was deposited under the voucher number MZUSP (145200). The remaining tadpoles are deposited at CLAR-UFRN (AAGARDA 3734).

Description. The body is slightly depressed dorso–ventrally and oval in dorsal and ventral views, with a triangular aspect in lateral view (fig. 1A, B, C). The snout is truncated in lateral view, and rounded in dorsal and ventral views. Eyes are small, located in the anterior third of body and positioned laterally. Nares are absent. A single ventral and medial spiracle, with a wide opening located in the last third of the body, sometimes covering the opening of the cloacal tube. The cloacal tube is short, medial, with the opening directed ventroposteriorly and fused with the ventral fin, without a free margin. The oral disc opening is terminal, without keratinized parts or papillae, and with short and paired semicircular dermal flaps in front of the mouth (Fig. 1D). The caudal musculature is moderately developed, tapering gradually to the posterior region. The maximum height of the ventral fin is slightly larger than the dorsal fin. The dorsal fin originates at the body and tail junction and gradually tapers anteroposteriorly to the tip of the tail. The lower tail fin margin is parallel to the body axis until the middle of the tail, after which it converges towards the tail tip.

Coloration. In life, body ranges from dark to light brown on the dorsal region, while lightly pale and slightly transparent on the ventral region. The dorsal and lateral regions present numerous dots, present in smaller numbers on the ventral region. The viscera are partially visible, and the tail has the same color patterns of the body. Pigmentation of the ventral edge of the fin scarce or absent, but always present on the dorsal edge.

Variation. We observed that *E. cesarii* tadpoles vary in body and tail muscle coloration according to development stage. In early stages the tadpoles present light pale pigmentation different from the tadpoles of advanced stages that present a dark brown pigmentation. Also, a thin light stripe in the first third of the tail occurs in some individuals in advanced stages.
