Abstract

Based on the analyses of specimens collected at several areas in the Cerrado domain from Central Brazil and others housed in scientific collections and on specimens collected at the type-locality, herein we describe three new species belonging to the *P. cristiceps* group: *Proceratophrys bagnoi* sp. nov., from UHE Serra da Mesa power plant ($13^{\circ}49'47.5''S$, $48^{\circ}19'17''W$; 570 m a.s.l.; WGS84 datum), Municipality of Minaçu, State of Goiás; *Proceratophrys branti* sp. nov., from Jalapão, Municipality of Mateiros ($05^{\circ}15'25''S$, $48^{\circ}12'00''W$; 109 m a.s.l.; WGS84 datum), State of Tocantins; and *Proceratophrys dibernardoi* sp. nov., Municipality of Mineiros ($17^{\circ}33'52''S$, $52^{\circ}33'20''W$; 803 m a.s.l.; WGS84 datum), State of Goiás. The diversity of *Proceratophrys* in Brazilian Cerrado is still underscored and several species will be described in the following years.

Key words: Amphibia, *Proceratophrys goyana*, *Proceratophrys bagnoi* sp. nov., *Proceratophrys branti* sp. nov., *Proceratophrys dibernardoi* sp. nov., Taxonomy

Introduction

Despite lacking a formal definition based on synapomorphies, the genus *Proceratophrys* Miranda-Ribeiro, 1920 is considered homogeneous based on overall morphology and it is likely a monophyletic taxon, with *Odontophrynus* Reinhardt & Lütken, 1862 + *Macrogenioglottus* Carvalho 1946 as its sister group (Frost *et al.* 2006; Pyron & Wiens 2011). All species in the genus share the following combination of characters: body without enlarged glands, absence of nuptial pads on thumbs, toes not webbed but laterally fringed, supernumerary tubercles present on hands and feet, dorsal surfaces of fingers and toes rugose, zygomatic ramus of squamosal bone close to or in sutural contact with maxilla, and cervical cotylar arrangement type II (cotyles closely approximated) (Savage and Cei 1965; Lynch 1971; Prado and Pombal 2008; Martins and Giaretta 2011). Currently, the genus is composed of 29 species (Ávila *et al.* 2012; Cruz *et al.* 2012; Frost 2013), distributed in four putative species groups based mainly on morphological traits (Kwet and Faivovich 2001; Giaretta *et al.* 2000; Prado and Pombal 2008; Cruz and Napoli 2010; Dias *et al.* 2013). These groups have not been accessed in a comprehensive phylogenetic analysis, and unfavorable evidence based on molecular data has been presented by Amaro *et al.* (2009), Pyron and Wiens (2011), Teixeira Jr. *et al.* (2012), and Dias *et al.* (2013). Herein we keep the traditional taxonomic arrangement for the genus, providing comparisons when necessary.

The *Proceratophrys bigibbosa* species group, characterized by the presence of developed postocular swellings and absence of prominent palpebral appendages, was reviewed by Kwet and Faivovich (2001) and includes *P.*

Acknowledgements

We thank Antonio Sebben, Janalee P. Caldwell, and Sheila Andrade for providing photos of adult individuals. To Ana Beatriz Costa and Taynã Rapp Py-Daniel for help with some photos and specimens measurements. To Miguel Vences, Natan Maciel and Adrian Garda for relevant comments on the manuscript and language improvements. UC acknowledges the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for financial support.
